(Received 4 January 2010; accepted 23 February 2010; published online 15 March 2010)

Due to the inherent property of large contact and parasitic resistances in amorphous InGaZnO (a-IGZO) thin film transistors (TFTs), a metal-semiconductor-metal (MSM) structure is a key element in a-IGZO TFTs. Therefore, voltage drops across resistances and MSM structure should be fully considered in the modeling and characterization of a-IGZO TFTs. A physics-based semiempirical model for the current-voltage characteristics of the MSM structure for the source-channel-drain contact in a-IGZO TFTs is proposed and verified with experimental results. The proposed model for the current in a-IGZO MSM structures includes a thermionic field emission \[ I_{TFE} \sim \exp(V_{R\text{-Schottky}}/V_T) \] and trap-assisted generation \[ I_{gen} \sim \sqrt{V_{R\text{-Schottky}}} \] in addition to the thermionic emission current \( I_F \) (Independent of the bias) under reverse bias. Experimental result suggests that electrical characteristics of the MSM structure depend not only on the Schottky barrier but also on the bulk property of the a-IGZO active layer. © 2010 American Institute of Physics.

Amorphous oxide thin film transistors (TFTs) are expected to be widely employed as switching devices for active-matrix liquid crystal displays/active-matrix organic light-emitting diodes because of the advantages in large scale integration, low cost room temperature (RT) fabrication process, high mobility, and compatibility with transparent and electronic paper applications.1 Characterization of the contact property between the source/drain (S/D) metal and the amorphous InGaZnO (a-IGZO) semiconductor active layer is important because a high series resistance in the S/D contacts causes degradation of electrical performance in threshold voltage \( V_T \), field effect mobility \( \mu_{FE} \), \( I_{on}/I_{off} \) ratio, subthreshold swing (SS), and other short channel effect.3

Due to large parasitic resistances inherent in a-IGZO TFTs, voltage drops across resistances should be considered in the modeling and characterization with the transfer length.3 For circuit applications of a-IGZO TFTs, physical mechanisms for the current transport should be considered in the modeling and characterization of the metal-semiconductor-metal (MSM) structure. In this work, a physics-based semiempirical model for the current transport in the MSM structure for S/D contacts is proposed and their modeling parameters are characterized for robust design and assessment of a-IGZO TFTs and their integrated circuits.

Fabricated TFTs have an inverted staggered bottom gate (thickness of SiO2: \( T_{SiO2} = 100 \) nm) with a-IGZO active layer \( T_{a-IGZO} = 70 \) nm deposited by rf magnetron sputtering at RT. The channel length \( L \), the width \( W \), and the overlap \( L_{ov} \) between the gate and S/D are designed to be \( L = 2 \) \( \mu m \), \( W = 200 \) \( \mu m \), and \( L_{ov} = 10 \) \( \mu m \), respectively. A schematic cross-section of the integrated a-IGZO TFTs is shown in the inset of Fig. 1(a) by the process sequence described in Ref. 4. Both the transfer and output characteristics of the fabricated a-IGZO TFT are shown in Figs. 1(a) and 1(b), respectively. Characteristic parameters are obtained to be \( V_T = -0.75 \) V, \( \mu_{FE} = 11.4 \) cm2/Vs, and \( SS = 370 \) mV/dec.

a-IGZO TFTs contain an MSM structure between the source-semiconducting a-IGZO active layer-drain due to the contact formation process on the semiconducting wide band gap a-IGZO layer (\( E_g > 3.0 \) eV). It can be electrically modeled as a series connection of two Schottky diodes with a resistor between them as shown in the inset of Fig. 2(a). The energy band diagram for the conduction mechanism in the MSM structure is schematically shown in Fig. 2(b) as an inset. In the S/D MSM structure, we obtain

\[
\begin{align*}
I_{DS} &= I_{R,\text{Schottky}} + I_{IGZO} = I_{F,\text{Schottky}}. \\
V_{DS} &= V_{R,\text{Schottky}} + V_{R} + V_{IGZO} + V_{F,\text{Schottky}} = V_{R,\text{Schottky}} + V_{IGZO} + V_{F,\text{Schottky}}.
\end{align*}
\]

FIG. 1. (Color online) (a) Measured transfer \( (I_{DS}-V_{DS}) \) characteristics with a schematic structure as an inset and (b) output \( (I_{DS}-V_{DS}) \) characteristics of the fabricated a-IGZO TFT with \( W/L = 200 \) \( \mu m/2 \) \( \mu m \).

\[ V_{R,\text{Schottky}} + V_{F,\text{Schottky}} \equiv V_{R,\text{Schottky}}, \]

(3)

with \( I_{DS}(V_{DS}) \): the drain current (voltage) across the MSM structure, \( I_{IGZO}(V_{IGZO}) \): Current (voltage) through the \( a \)-IGZO active layer, \( I_{R,\text{Schottky}}(V_{R,\text{Schottky}}) \) and \( I_{R,\text{Schottky}}(V_{R,\text{Schottky}}) \): Current (voltage) across the reverse- and forward-biased Schottky diodes, and \( V_{F} \): Voltage drop across the S/D parasitic resistance. Current in the MSM structure for the S/D contact is limited by the reverse biased Schottky contact and there are mainly three current components: (i) thermal generation current \( (J_{\text{gen}}) \), (ii) thermionic field emission current \( (J_{\text{TFE}}) \), and (iii) thermionic emission current \( (J_{g}) \) in the reverse biased Schottky diode (Ref. 5).

Investigating the bias-dependence of the current in the experimental data, the trap-assisted generation current \( (J_{\text{gen}}) \) (Ref. 6) in the space charge region (SCR) is observed to be the main component under a low drain bias [Fig. 2(a)]. Although the band gap energy of the \( a \)-IGZO layer is very high (~3 eV), trapped electrons under the Fermi level \( (E_{F}) \) in the \( a \)-IGZO channel layer can be thermally excited through the subgap energy states distributed over the band gap. On the other hand, the thermionic field emission current \( (J_{\text{TFE}}) \) (Ref. 7) is dominant under a large reverse bias [Fig. 2(b)].

The trap-assisted thermal generation current \( J_{\text{gen}} \) through traps in the SCR is described by

\[ J_{\text{gen}} = q \int_{0}^{X} g_{\text{act}} \, dx = J_{00} \sqrt{1 + \frac{V_{R,\text{Schottky}}}{V_{th}}} \times \left[ 1 - \exp\left(-\frac{V_{R,\text{Schottky}}}{V_{th}}\right) \right] \left[A/cm^{2}\right], \]

(4)

\[ J_{00} = \frac{q \, n_{\text{r}} \, \tau_{\text{r}}}{2 \, \tau_{\text{i}}} \sqrt{\frac{2 \, e_{\text{IGZO}} \, V_{th}}{q \, N_{D}}} \left[A/cm^{2}\right], \]

(5)

where \( n_{\text{r}}, \tau_{\text{r}}, e_{\text{IGZO}}, N_{D}, \) and \( V_{th} \) are the intrinsic carrier density, lifetime, permittivity, donor density in the \( a \)-IGZO active layer, and the built-in voltage in the Schottky contact, respectively. We note that \( J_{\text{gen}} \) is proportional to \( \sqrt{1 + \frac{V_{R,\text{Schottky}}}{V_{th}}} \) and the characteristic current density \( J_{00} \) is determined by the bulk property of the \( a \)-IGZO layer.

The thermionic field emission current \( J_{\text{TFE}} \), formed by thermal excitation of electrons and continuous tunneling through the Schottky barrier from the metal to the \( a \)-IGZO channel layer under large reverse bias and, is described by

\[ J_{\text{TFE}} = J_{\text{TFE}0} \exp\left(\frac{q \, V_{R,\text{Schottky}}}{E'}\right), \]

(6)

\[ J_{\text{TFE}0} = \frac{A^{*} \, T^{2} \sqrt{\pi \, E_{0}}}{kT} \sqrt{q \, V_{R} + \frac{E_{B}}{\cosh(E_{0}/kT)}} \exp\left(-\frac{E_{B}}{E_{0}}\right), \]

(7)

\[ E' = E_{00} \left[ \frac{E_{00}}{kT} - \tanh\left(\frac{E_{00}}{kT}\right) \right], \]

\[ E_{0} = E_{00} \cosh(E_{00}/kT), \quad E_{00} = \frac{\hbar}{2} \sqrt{m_{\text{IGZO}}^{*} \cdot N_{D}}, \]

where \( A^{*}, T, E_{B}, \hbar, \) and \( m_{\text{IGZO}}^{*} \) are the Richardson constant, temperature, Schottky barrier, the Plank constant, and the effective mass of electrons in the \( a \)-IGZO layer, respectively. \( E' \), \( E_{0} \), and \( E_{00} \) are characteristic energies for the thermionic field emission current. We also note that \( J_{\text{TFE}} \) is proportional to \( \exp(q \, V_{R,\text{Schottky}}/E') \).

The thermionic emission current \( J_{g} \) is formed by electrons overcoming the Schottky barrier by the thermal energy from the metal to the \( a \)-IGZO channel layer. It is described by

\[ J_{g} = A^{*} \, T^{2} \exp(-E_{B}/kT) \] and independent of the reverse bias. Therefore, the dominant mechanisms across the MSM structure are expected to be the trap-assisted generation current \( J_{\text{gen}} \) and the thermionic field emission current \( J_{\text{TFE}} \) under reverse bias as described by

\[ J_{R,\text{Schottky}} = J_{\text{gen}} + J_{\text{TFE}} + J_{g}. \]

(9)

The property of contacts on the \( a \)-IGZO layer depends not only on the Schottky barrier \( E_{B} \) but also on the bulk property of the \( a \)-IGZO channel layer. Therefore, it is strongly subject to the fabrication process such as rf power, \( O_{2} \) partial pressure, and thickness of the \( a \)-IGZO active layer.

Due to the inherent property of \( a \)-IGZO TFTs, the voltage drop across large channel and parasitic resistances should be considered in the modeling and characterization of the MSM structure. The total resistance is composed of the external load resistance \( (R_{L}) \), source resistance \( (R_{S}) \), drain resistance \( (R_{D}) \), and \( V_{GS} \)-dependent channel resistance \( (R_{cb}) \). The contact resistance \( (R_{C}=R_{S}+R_{D}) \) can be extracted by using the modified external loading method, connecting an external load resistor to the source terminal. Considering the voltage drop on resistances, the drain current \( I_{DS} \) in TFTs under linear operation is described by

\[ I_{DS} = K \left[ V_{GS} - I_{DS}(R_{S} + R_{L}) - V_{T} - 0.5 \left[ V_{DS} - I_{DS}(R_{S} + R_{D} + R_{L}) \right] \right] \times \left[ V_{DS} - I_{DS}(R_{S} + R_{D} + R_{L}) \right], \]

(10)

where \( K = \mu C_{ox}(W/L) \) with \( \mu \) = the channel carrier mobility and \( C_{ox} \) = the effective gate capacitance per unit area \( (F/cm^{2}) \). Under linear mode of operation with a small drain bias \( V_{DS} \), we obtain

\[ \frac{1}{I_{DS}} = \frac{R_{L} + R_{S} + R_{D}}{V_{DS}} + \frac{1}{K \left( V_{GS} - V_{T} - 0.5 V_{DS} \right) V_{DS}}. \]

(11)

By plotting \( 1/I_{DS} \) versus \( R_{S} \), as a function of \( V_{GS}, R_{L} \) from the intercept in Fig. 3(a) can be obtained to be...
By plotting the $V_{GS}$-dependent $-R_L$ as a function of $1/(V_{GS}-V_T-0.5V_{DS})$, the total resistances from two $I_{DSV_{DS}}$ curves are extracted to be almost the same as $R_{T,\text{gate floating}}=121$ kΩ when the gate electrode is floated and $R_{T,VV_{SSO}}=132$ kΩ at $V_{GS}=0$ V. Since we modeled that $R_C=R_S+R_D$ is independent of $V_{GS}$, the difference in the total resistance is caused by the $V_{GS}$-dependent channel resistance. With $V_{GS}$-dependent channel resistance, the S/D contact resistance is extracted to be $R_C=42.6$ kΩ. Each voltage drop in the channel and contact region is calculated considering the extracted resistance from experimental data shown in Fig. 3(b) as an inset.

Extraction of model parameters using the physics-based model for the MSM structure in the α-IGZO TFT is shown in Fig. 4(a). The Schottky barrier, denoted in the inset of Fig. 4(a), of the contact from the thermionic emission current component $J_{\text{therm}}$ is obtained to be $E_0=0.216$ eV. By plotting $\sqrt{(1+V_{R,\text{Schottky}}/V_b)}$ versus $I_D$ in the $J_{\text{gen}}$-dominant region, $V_b$ can be obtained from the intersection in Fig. 4(a). On the other hand, by plotting $V_{R,\text{Schottky}}$ versus $\log(I_D)$ in the $J_{\text{TEE}}$-dominant region where $J_{\text{TEE}}$ is proportional to $\exp(qV_{R,\text{Schottky}}/E')$, $N_D$ is extracted from the slope in Fig. 4(a). In Fig. 4(b) for $V_{GS}=0$ V, $I_{DSV_{DS}}$ characteristics of the α-IGZO MSM structure are compared with the physics-based semiempirical model for the effective contact area $A_{\text{eff}}=100$ μm$^2$ considering the channel width and the transfer length of the metal contact. Experimental I-V curve agrees well with the physics-based semiempirical model adopting experimentally extracted model parameters ($J_{\text{geo}}=526.7$ A/cm², $\tau_0=2.73$ μs, $\varepsilon_{\text{IGZO}}=11.5$, $\varepsilon_o$, $N_D=1.01 \times 10^{17}$ cm$^{-3}$, $m_{\text{IGZO}}=0.15m_o$, and $V_b=0.097$ V).

In conclusion, voltage drops across resistances should be considered in the modeling and characterization because α-IGZO TFTs contain an MSM structure due to inherent property of large contact and parasitic S/D resistances. A physics based semiempirical model for the current-voltage characteristics of the source-channel-drain MSM contact in α-IGZO TFTs was proposed, model parameters are extracted, and verified by comparison of the experimental data. In the model for α-IGZO MSM structures, a thermionic field emission and trap-assisted generation were considered in addition to the thermionic emission current under reverse bias. Experimental result suggests that contact characteristics are strongly dependent not only on the Schottky barrier but also on the bulk property of the α-IGZO active layer.
